## Functional Programming in R

We'll cover slightly more complex functions.

Map, Filter, Reduce, et al.

Map(), Filter(), and Reduce()

Here's a brief overview of the functions we'll be learning about:

- mapply() applies a function (which accepts multiple parameters) over multiple vectors of arguments, calling the function on the first element of each list, then the second elements, and so on and so forth.
  - Precisely, it accepts as input a function func and N equivalently-sized lists of arguments args1, ..., argsN, each of length k. It returns as output a list containing func(args1[1], ..., argsN[1]), func(arg1[2], ..., argsN[2]), ..., func(args1[k], ..., argsN[k]).
- Map() is a wrapper for mapply() that calls it with the parameter simplify=FALSE.
