In certain situations, you might want to subset with a *matrix*. Again, at this point, don't worry too much about what a matrix *is*.

Exercise. With the previously defined 10-by-10 data frame, set df[5, 5] = NA; df[6, 6] = NA. Figure out how df[is.na(df)] works. Write and test a function that takes as input a data frame df of purely numeric data and a number k, returning a vector of every number in df divisible by k.
